4 Dual simplex algorithm

5 Software tools for LP
Standard form LP

$$\text{min } c^T x$$

s.t. $Ax = b,$

$x \geq 0.$

$A \in \mathbb{R}^{m \times n}, \ h(A) = m,$ non-degenerate (basic solutions have $m$ positive elements).

$$M = \{x \in \mathbb{R}^n : Ax = b, \ x \geq 0\}.$$
Decomposition of $M$:

- **Convex polyhedron** $P$ – uniquely determined by its vertices (convex hull)
- **Convex polyhedral cone** $K$ – generated by extreme directions (positive hull)

**Direct method** (evaluate all vertices and extreme directions ...)

1. \( M = \emptyset \)
2. \( M \neq \emptyset \): the problem is unbounded
3. \( M \neq \emptyset \): the problem has an optimal solution (at least one of the solutions is vertex)

Simplex algorithm – basis

**Basis** \( B = \text{regular square submatrix of } A \), i.e.

\[
A = (B|N).
\]

We also consider \( B = \{i_1, \ldots, i_m\} \).

We split the objective coefficients and the decision vector accordingly:

\[
c^T = (c_B^T, c_N^T),
\]

\[
x^T(B) = (x_B^T(B), x_N^T(B)),
\]

where

\[
B \cdot x_B(B) = b, \quad x_N(B) \equiv 0.
\]

- Feasible basis, optimal basis ..
- Basic solution(s) ..
Simplex algorithm – simplex table

<table>
<thead>
<tr>
<th>$c_B$</th>
<th>$x_B$</th>
<th>$B^{-1}b$</th>
<th>$B^{-1}A$</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>$c_B^T B^{-1}b$</td>
<td>$c_B^T B^{-1}A - c^T$</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Feasibility condition:
\[ B^{-1}b \geq 0. \]

Optimality condition:
\[ c_B^T B^{-1}A - c^T \leq 0. \]
Simplex algorithm – a step

- Denote the criterion row by
  \[ \delta^T = c_B^T B^{-1} A - c^T. \]
- Find \( \delta_i > 0 \) and denote the corresponding column by
  \[ \rho = B^{-1} A_{.,i}. \]
- Minimize the ratios
  \[ \hat{u} = \arg\min \left\{ \frac{x_u(B)}{\rho_u} : \rho_u > 0, \ u \in B \right\}. \]
- Substitute \( x_{\hat{u}} \) by \( x_i \) in the basic variables, i.e. \( \hat{B} = B \setminus \{\hat{u}\} \cup \{i\} \).
Denote by $\hat{B}$ the new basis, i.e. $\hat{B} = B \setminus \{\hat{u}\} \cup \{i\}$.

Define a direction

$$\Delta_u = -\rho_u, \ u \in B,$$
$$\Delta_i = 1,$$
$$\Delta_j = 0, \ j \notin B \cup \{i\}.$$ 

If $\rho \leq 0$, then the problem is unbounded ($c^T x(\hat{B}) \rightarrow -\infty$). Otherwise, we can move from the current basic solution to another one

$$x(\hat{B}) = x(B) + t\Delta,$$

where $0 \leq t \leq \frac{x_{\hat{u}}(B)}{\rho_{\hat{u}}}$. We should prove that the new solution is a feasible basic solution ($\hat{B}$ is regular, $x(\hat{B}) \geq 0$, $\hat{B}x(\hat{B}) = b$) and that the objective value decreases ...
Simplex algorithm – pivot rules

... rules for selecting the entering variable if there are several possibilities:

- **Largest coefficient** in the objective function
- **Largest decrease** of the objective function
- **Steepest edge** – choose an improving variable whose entering into the basis moves the current basic feasible solution in a direction closest to the direction of the vector \( c \)

\[
\max \frac{c^T(x_{\text{new}} - x_{\text{old}})}{\|x_{\text{new}} - x_{\text{old}}\|}.
\]

Computationally the most successful.

- **Blands’s rule** – choose the improving variable with the smallest index, and if there are several possibilities for the leaving variable, also take the one with the smallest index (prevents cycling)

Matoušek and Gärtner (2007).

Transportation problem

- \( x_{ij} \) – decision variable: amount transported from \( i \) to \( j \)
- \( c_{ij} \) – costs for transported unit
- \( a_i \) – capacity
- \( b_j \) – demand

**ASS.** \( \sum_{i=1}^{n} a_i \geq \sum_{j=1}^{m} b_j \).
(Sometimes \( a_i, b_j \in \mathbb{N} \).)
Transportation problem

Primal problem

\[
\begin{align*}
\text{min} & \quad \sum_{i=1}^{n} \sum_{j=1}^{m} c_{ij} x_{ij} \\
\text{s.t.} & \quad \sum_{j=1}^{m} x_{ij} \leq a_i, \quad i = 1, \ldots, n, \\
& \quad \sum_{i=1}^{n} x_{ij} \geq b_j, \quad j = 1, \ldots, m, \\
& \quad x_{ij} \geq 0.
\end{align*}
\]
Transportation problem

Dual problem

\[
\max \sum_{i=1}^{n} a_i u_i + \sum_{j=1}^{m} b_j v_j \\
\text{s.t. } u_i + v_j \leq c_{ij}, \\
\quad u_i \leq 0, \\
\quad v_j \geq 0.
\]

Interpretation: 
\(-u_i\) price for buying a unit of goods at \(i\), \(v_j\) price for selling at \(j\).
Transportation problem

Competition between the transportation company (which minimizes the transportation costs) and an “agent” (who maximizes the earnings):

\[
\sum_{i=1}^{n} a_i u_i + \sum_{j=1}^{m} b_j v_j \leq \sum_{i=1}^{n} \sum_{j=1}^{m} c_{ij} x_{ij}
\]
Primal problem

\[(P) \quad \min c^T x \]
\[\text{s.t. } Ax \geq b, \]
\[x \geq 0.\]

and corresponding dual problem

\[(D) \quad \max b^T y \]
\[\text{s.t. } A^T y \leq c, \]
\[y \geq 0.\]
Denote

\[ M = \{ x \in \mathbb{R}^n : Ax \geq b, \quad x \geq 0 \}, \]
\[ N = \{ y \in \mathbb{R}^m : A^T y \leq c, \quad y \geq 0 \}, \]

**Weak duality theorem:**

\[ b^T y \leq c^T x, \quad \forall x \in M, \forall y \in N. \]

Equality holds if and only if (iff) complementarity slackness conditions are fulfilled:

\[ y^T (Ax - b) = 0, \]
\[ x^T (A^T y - c) = 0. \]
Apply KKT optimality conditions to primal LP …
Duality in linear programming

Duality theorem: If $M \neq \emptyset$ and $N \neq \emptyset$, than the problems (P), (D) have optimal solutions.

Strong duality theorem: The problem (P) has an optimal solution if and only if the dual problem (D) has an optimal solution. If one problem has an optimal solution, than the optimal values are equal.
Linear programming duality

**Primal problem** (standard form)

\[
\begin{align*}
\text{min} & \quad c^T x \\
\text{s.t.} & \quad Ax = b, \\
& \quad x \geq 0.
\end{align*}
\]

and corresponding **dual problem**

\[
\begin{align*}
\text{max} & \quad b^T y \\
\text{s.t.} & \quad A^T y \leq c, \\
& \quad y \in \mathbb{R}^m.
\end{align*}
\]
Dual simplex algorithm

- Basic dual solution
- Dual basis
Dual simplex algorithm

Optimality condition:
\[ c_B^T B^{-1} A - c^T \leq 0. \]

After rearranging the columns we have
\[ A = (B|N), \quad c^T = (c_B^T, c_N^T), \]
thus
\[ c_B^T B^{-1} B - c_B^T = 0, \]
\[ c_B^T B^{-1} N - c_N^T \leq 0, \]

Setting \( \hat{u} = (B^{-1})^T c_B \)
\[ B^T \hat{u} = c_B^T, \]
\[ N^T \hat{u} \leq c_N^T. \]

Thus, \( \hat{u} \) is a dual feasible solution.
Dual simplex algorithm – a step

... uses the same simplex table.

- Find index \( u \in B \) such that \( x_u(B) < 0 \) and denote the corresponding row by
  \[
  \tau^T = (B^{-1}A)_{u,:}.
  \]

- Denote the criterion row by
  \[
  \delta^T = c^T_B B^{-1}A - c^T \leq 0.
  \]

- Minimize the ratios
  \[
  \hat{i} = \arg \min \left\{ \frac{\delta_i}{\tau_i} : \tau_i < 0 \right\}.
  \]

- Substitute \( x_u \) by \( x_{\hat{i}} \) in the basic variables, i.e. \( B = B \setminus \{u\} \cup \{\hat{i}\} \).
Example – dual simplex algorithm

\[ \begin{align*}
\text{min} & \quad 4x_1 + 5x_2 \\
\quad x_1 + 4x_2 & \geq 5, \\
\quad 3x_1 + 2x_2 & \geq 7, \\
\quad x_1, x_2 & \geq 0.
\end{align*} \]
